

Authentication Protocols (CS-352)

Authentication Protocols

- Used to convince parties of each other's **identity** and to exchange session keys

Authentication Protocols

- Published protocols are often found to have flaws and need to be modified
- Key issues are
 - ◆ Confidentiality
 - To prevent **masquerade** and to prevent **compromise of session keys**, essential identification and session key information must be communicated in encrypted form.
 - ◆ Timeliness – to prevent **replay attacks**

Replay Attacks

- A valid signed message is copied and later resent
 - ◆ **Simple replay:** the opponent simply copies a message and replays it later

Replay Attacks

- A valid signed message is copied and later resent
 - ◆ **Repetition that can be logged:** an opponent can replay a timestamped message within the valid time window
 - ◆ **Repetition that cannot be detected:** may arise because the original message could have been suppressed and thus did not arrive at its destination; only the replay message arrives.

Replay Attacks

- A valid signed message is copied and later resent
 - ◆ **Backward replay without modification:** a replay back to the sender
 - When using symmetric encryption, the sender cannot easily recognize the difference between messages sent and messages received.

Replay Attacks

• Countermeasures

- ◆ Attach a **sequence number** to each message used in an authentication exchange
 - Generally impractical – requires each party to keep track of the last sequence number for each claimant it has dealt with
- ◆ **Timestamps**: party A accepts a message as fresh only if the message contains a timestamp that, in A's judgment, is close enough to A's knowledge of current time.
 - Needs synchronized clocks

Replay Attacks (Cont.)

● Countermeasures

◆ **Nonce:** a random number that illustrates the freshness of a session.

- Party A sends B a nonce and requires that the subsequent response received from B contains the correct nonce value.

Using Symmetric Encryption

- As discussed previously can use a **two-level** hierarchy of keys
- Usually with a trusted **Key Distribution Center (KDC)**
 - ◆ Each party shares own **master key** with KDC
 - ◆ KDC generates **session keys** used for connections between parties
 - ◆ Master keys used to distribute these to them

Needham-Schroeder Symmetric Key Protocol (Revisited)

- Original third-party key distribution protocol
- For session between A B mediated by **KDC**
- Protocol:

1. **A**->**KDC**: $ID_A \parallel ID_B \parallel N_1$
2. **KDC** -> **A**: $E_{K_a}[K_s \parallel ID_B \parallel N_1 \parallel E_{K_b}[K_s \parallel ID_A]]$
3. **A** -> **B**: $E_{K_b}[K_s \parallel ID_A]$
4. **B** -> **A**: $E_{K_s}[N_2]$
5. **A** -> **B**: $E_{K_s}[f(N_2)]$

Needham-Schroeder Symmetric Key Protocol (Revisited)

3. A \rightarrow B: $E_{K_b}[K_s || ID_A]$

4. B \rightarrow A: $E_{K_s}[N_2]$

5. A \rightarrow B: $E_{K_s}[f(N_2)]$

- Suppose that an attacker **X** has been able to compromise an old session key.

Attack: Needham-Schroeder Protocol (Revisited)

3. $A \rightarrow B: E_{K_b}[K_s || ID_A]$

4. $B \rightarrow A: E_{K_s}[N_2]$

5. $A \rightarrow B: E_{K_s}[f(N_2)]$

- Suppose that an attacker **X** has been able to compromise an old session key.
- **X** can impersonate **A** and trick **B** into using the old key by simply **replaying step 3**.
- Unless **B** remembers indefinitely all previous session keys used with **A**, **B** will be unable to determine that this is a replay.
- **X** then **intercepts the step 4** and sends bogus messages to **B** that appear to **B** to come from **A** using an authenticated session key.

Solution: Needham-Schroeder Protocol (Revisited)

- Use a **timestamp T** that assures A and B that the session key has only just been generated.

- Revised protocol:

1. **A → KDC:** $ID_A \parallel ID_B \parallel N_1$
2. **KDC → A:** $E_{K_a}[K_s \parallel ID_B \parallel N_1 \parallel E_{K_b}[K_s \parallel ID_A \parallel T]]$
3. **A → B:** $E_{K_b}[K_s \parallel ID_A \parallel T]$
4. **B → A:** $E_{K_s}[N_2]$
5. **A → B:** $E_{K_s}[f(N_2)]$

Timestamp

- Principals can verify the timeliness by checking:

$$|\text{Clock} - T| < \Delta t_1 + \Delta t_2$$

- ◆ Δt_1 : The estimated normal discrepancy between the KDC's clock and the local clock (principals' clock)
- ◆ Δt_2 : The expected network delay time

- Need to **synchronize clock**

Suppress-Replay Attacks

- **Suppress-replay attacks:** when the sender's clock is ahead of the receiver's clock, the opponent can intercept a message from the sender and replay it later when the timestamp in the message becomes current at the receiver's site.

Suppress-Replay Attacks

- **Suppress-replay attacks:** when the sender's clock is ahead of the receiver's clock, the opponent can intercept a message from the sender and replay it later when the timestamp in the message becomes current at the receiver's site.
- **Countermeasure:**
 - ◆ Enforce the requirement that parties regularly check their clocks against the KDC's clock.
 - ◆ Rely on handshaking protocols using **nonces**.

Using Public-Key Encryption

- Have a range of approaches based on the use of public-key encryption
- Need to ensure we have correct public keys for other parties
- Various protocols exist using timestamps or nonces

Needham-Schroeder Public Key Protocol

[Lowe, 1995]

Needham-Schroeder Public Key Protocol

[Lowe, 1995]

Needham-Schroeder-Lowe Public Key Protocol

One-Way Authentication

- Required when sender and receiver are **not** in communications at same time (eg. **email**)
- Have header in clear so can be delivered by email system
- May want contents of body protected & sender authenticated

Using Symmetric Encryption

• Can refine use of KDC but cannot have exchange of nonces:

1. A → KDC: $ID_A \parallel ID_B \parallel N_I$
2. KDC → A: $E_{K_a}[K_s \parallel ID_B \parallel N_I \parallel E_{K_b}[K_s \parallel ID_A]]$
3. A → B: $E_{K_b}[K_s \parallel ID_A] \parallel E_{K_s}[M]$

Using Symmetric Encryption

- Can refine use of KDC but cannot have exchange of nonces:

1. A → KDC: $ID_A \parallel ID_B \parallel N_I$
2. KDC → A: $E_{K_a}[K_s \parallel ID_B \parallel N_I \parallel E_{K_b}[K_s \parallel ID_A]]$
3. A → B: $E_{K_b}[K_s \parallel ID_A] \parallel E_{K_s}[M]$

- Guarantees that only the **intended recipient** of a message will be able to read it.
- Does not protect against **replays**
 - ◆ Could rely on timestamp in message, though email delays make this problematic

Secure Sockets Layer/Transport Layer Security (SSL/TLS) and Web Security

Web Security

- World Wide Web is fundamentally a **client/server application** running over internet and TCP/IP intranet.
- Web now widely used by business, government, individuals
- But Web is **vulnerable**

Example of a Web Vulnerability (1)

Website: <http://asi.fullerton.edu/VirtualEMS/Login.aspx>

Steps:

- ◆ Enter user name: **mgofman**
- ◆ Enter password: **s3sec**
- ◆ Use **WireShark** packet sniffer to observe the website traffic...

Example of a Web Vulnerability (2)

- Traffic captured using Wireshark:

Wireshark 1.8.2 interface showing captured traffic on interface eth0. The filter is set to http. The packet list shows several HTTP requests and responses. The packet details pane for packet 114 shows a URL with a highlighted section:

```

Summary of Web-based Attacks

	Threats	Consequences	Countermeasures
Integrity	<ul style="list-style-type: none">• Modification of user data• Trojan horse browser• Modification of memory• Modification of message traffic in transit	<ul style="list-style-type: none">• Loss of information• Compromise of machine• Vulnerability to all other threats	Cryptographic checksums
Confidentiality	<ul style="list-style-type: none">• Eavesdropping on the net• Theft of info from server• Theft of data from client• Info about network configuration• Info about which client talks to server	<ul style="list-style-type: none">• Loss of information• Loss of privacy	Encryption, Web proxies
Denial of Service	<ul style="list-style-type: none">• Killing of user threads• Flooding machine with bogus requests• Filling up disk or memory• Isolating machine by DNS attacks	<ul style="list-style-type: none">• Disruptive• Annoying• Prevent user from getting work done	Difficult to prevent
Authentication	<ul style="list-style-type: none">• Impersonation of legitimate users• Data forgery	<ul style="list-style-type: none">• Misrepresentation of user• Belief that false information is valid	Cryptographic techniques

Hypertext Transfer Protocol Secure (HTTPS)

- A combination of the http protocol and a network security protocol
- Also known as **Hypertext Transfer Protocol over Secure Socket Layer**

Hypertext Transfer Protocol Secure (HTTPS)

- The administrator must create a **public X.509 key certificate** for the Web server.
- This certificate must be signed by a certificate authority.
 - **SSL certificate providers:** Verisign, Thawte, InstantSSL, Entrust, Baltimore, Geotrust etc.
- Web browsers are distributed with the public key of major certificate authorities so that they can verify certificates signed by them.

SSL/TLS (Secure Socket Layer/Transport Layer Security)

- A cryptographic protocol that provides security for communications over networks.
- One of the most widely used Web security mechanisms.
- **Transport layer security service** - designed to make use of TCP to provide a reliable end-to-end security service.
- Originally developed by **Netscape**
- Subsequently became Internet standard known as **TLS (Transport Layer Security)**

SSL/TLS Architecture

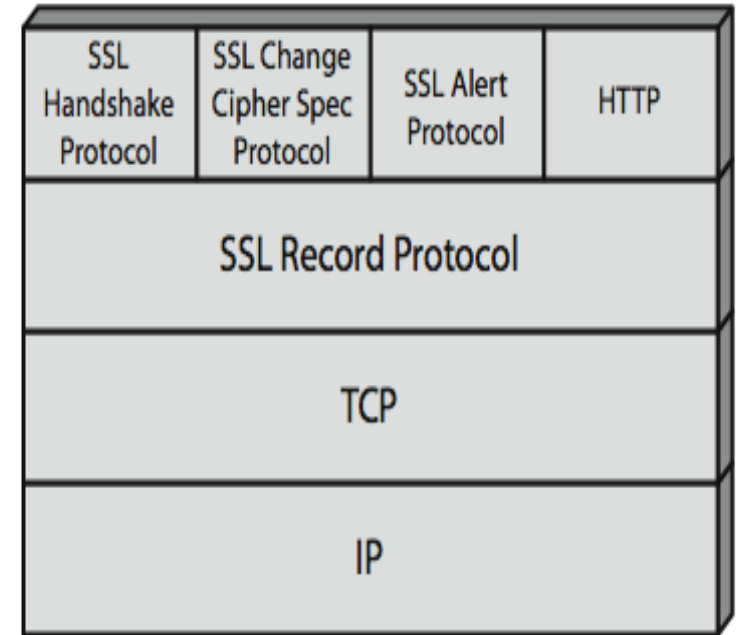

• Has two layers of protocols

◆ **Level 1:**

- **SSL Record Protocol:** provides basic security services to various higher-layer protocols.

◆ **Level 2:**

- **Hypertext Transfer Protocol (HTTP):** which provides the transfer service for Web client/server interaction, can operate on top of SSL.
- **Three higher-layer protocols:** used in the management of SSL exchanges.

SSL/TLS Handshake Protocol

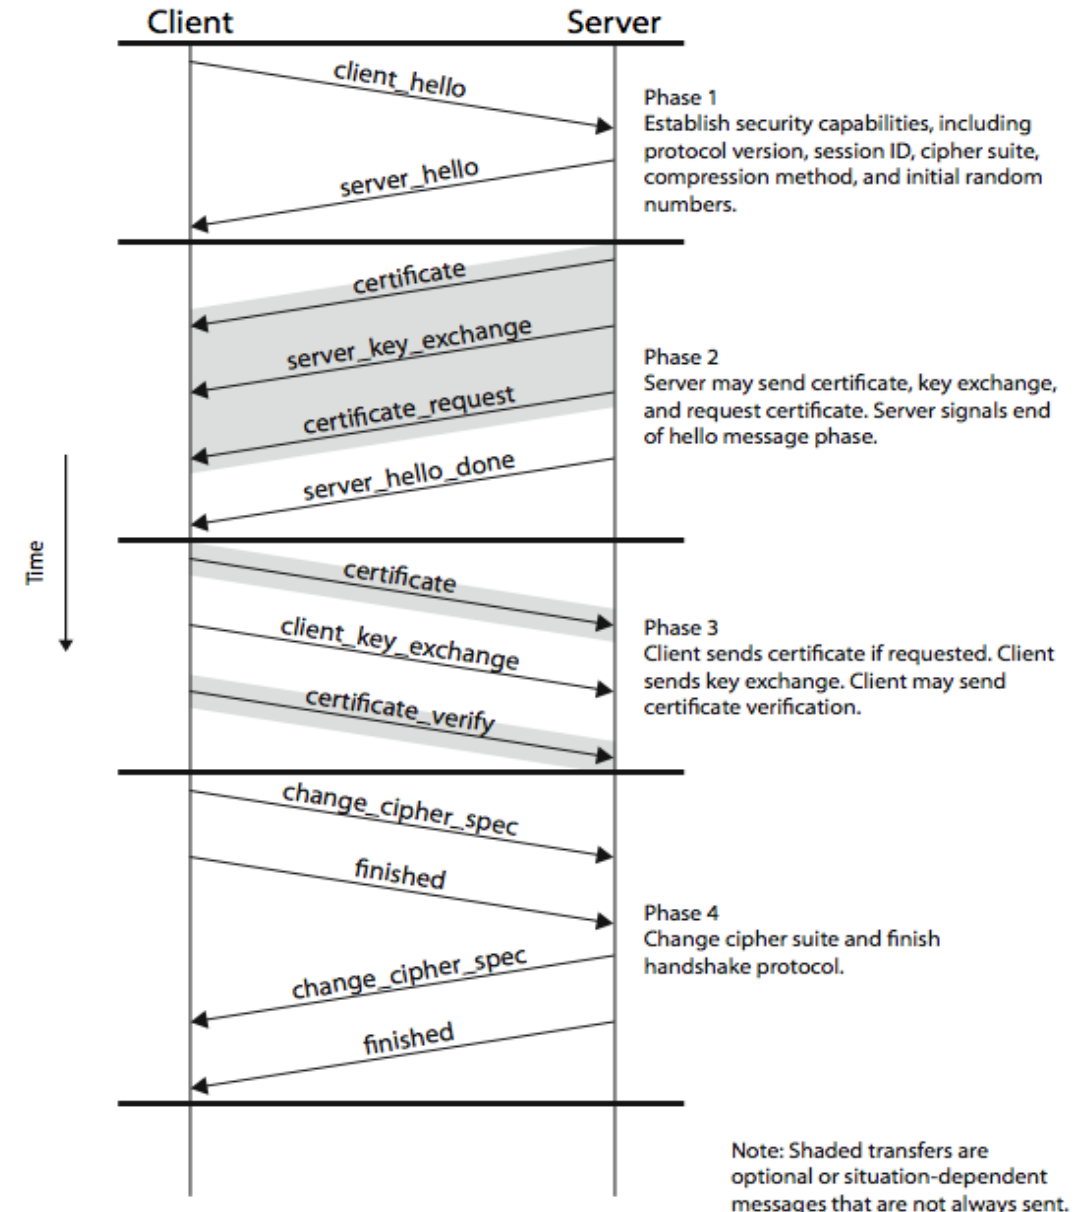

- Allows **server** and **client** to:
 - ◆ Authenticate each other
 - ◆ To negotiate encryption & MAC algorithms
 - ◆ To negotiate cryptographic keys to be used to protect data sent in an SSL record.

SSL/TLS Handshake Protocol

Comprises a series of messages in phases

1. Establish Security Capabilities:

(a) The client initiates a **logical connection** and establish the **security capabilities**: protocol version, session ID, cipher suite (**cryptographic algorithms** supported by the client), compression method.

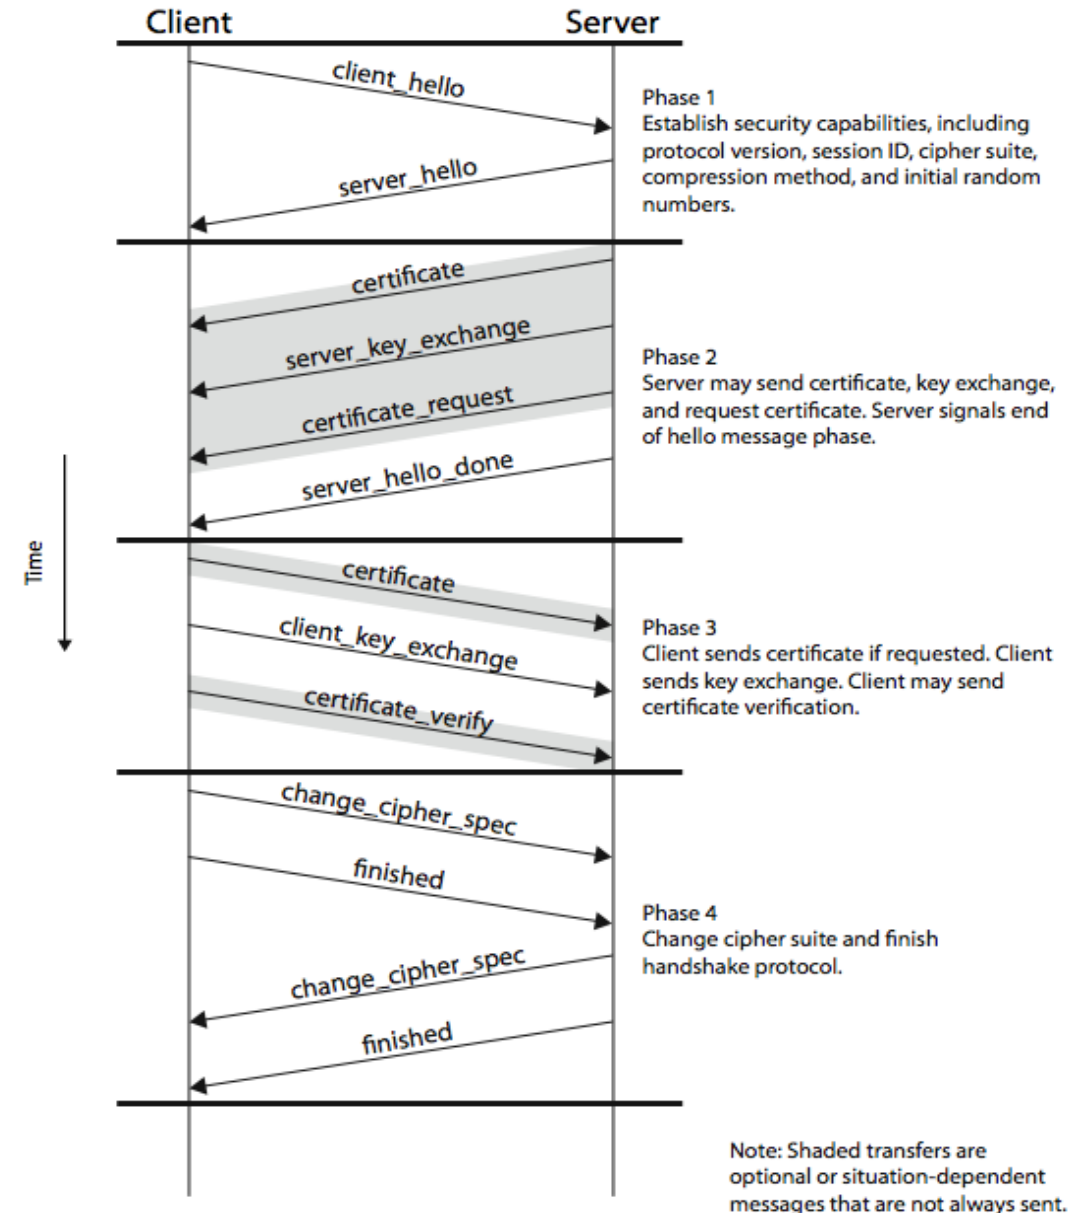

SSL/TLS Handshake Protocol

Comprises a series of messages in phases

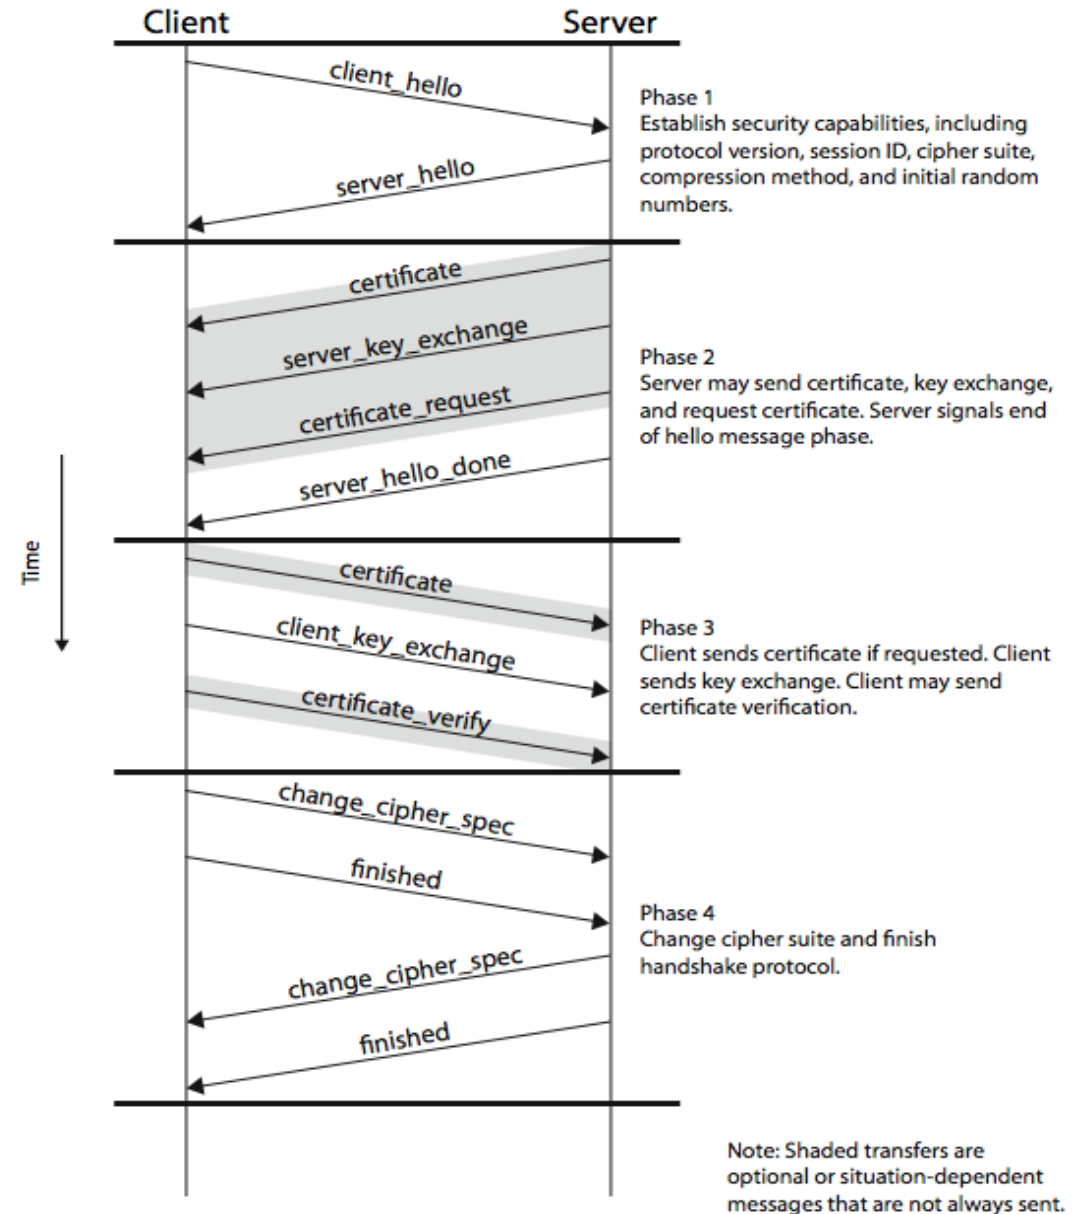

1. Establish Security Capabilities:

(b) the server picks the strongest cipher and hash function that it also supports and notifies the client of the decision

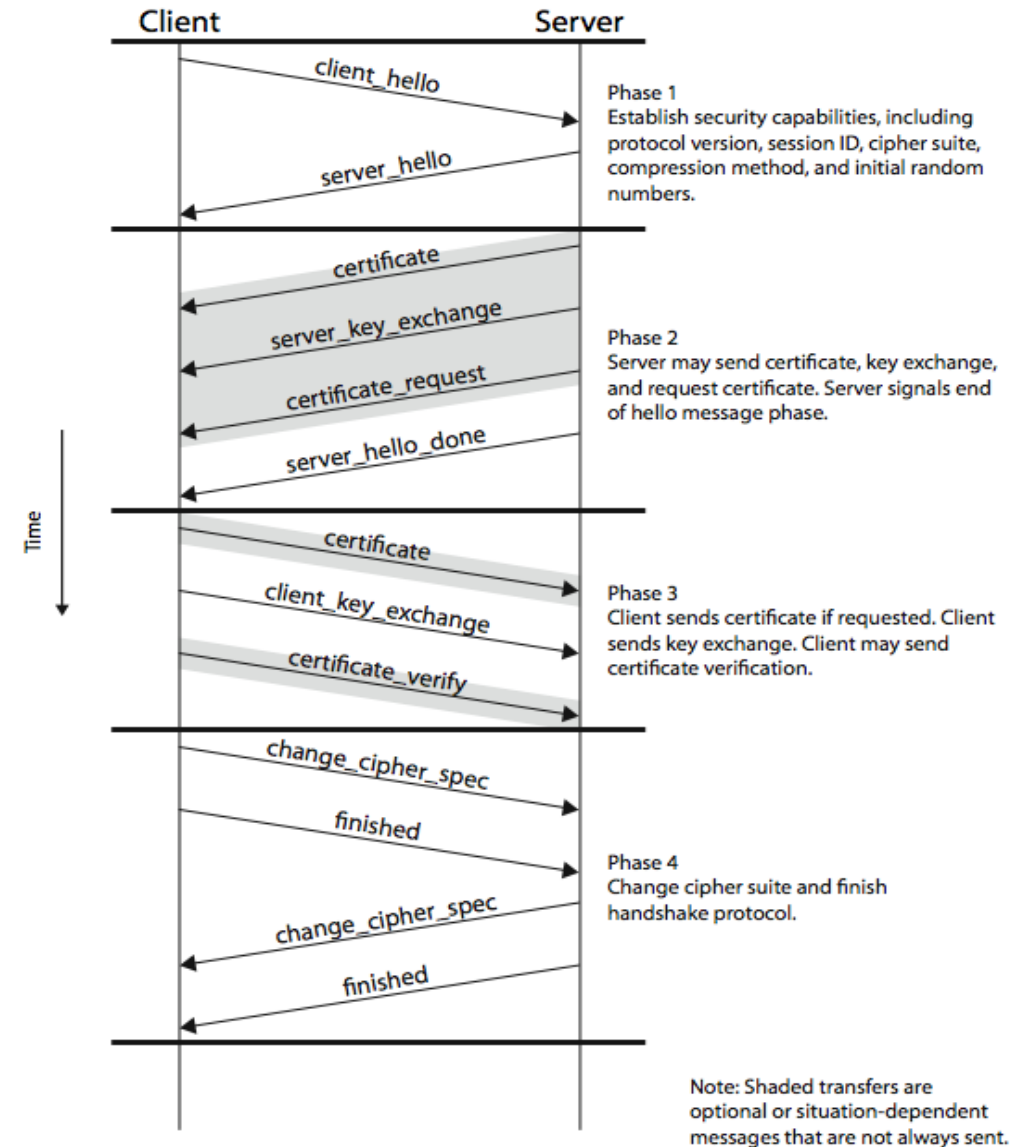

SSL/TLS Handshake Protocol

2. **Server Authentication and Key Exchange:** 1) sends certificate if it needs to be authenticated; 2) sends a `server_key_exchange` message, and request certificate; 3) signals the end of hello message phase.

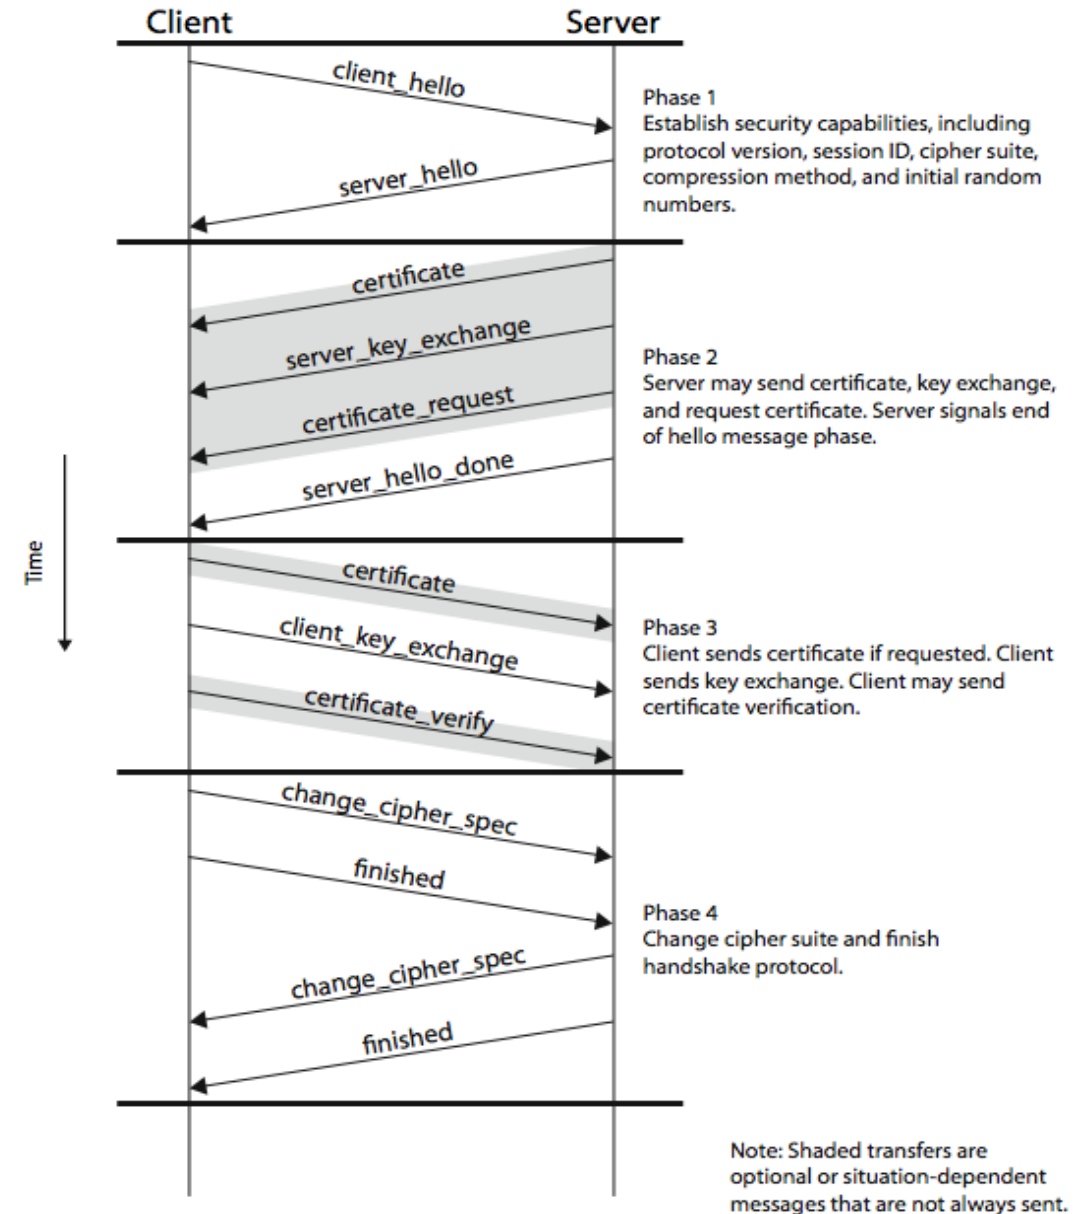

SSL/TLS Handshake Protocol

3. Client Authentication and Key Exchange:
sends certificate if requested and encrypts a random key with the server's public key, and sends the result to the server.

SSL/TLS Handshake Protocol

4. Change **cipher suite** and finish handshake protocol.

SSL/TLS Change Cipher Spec Protocol

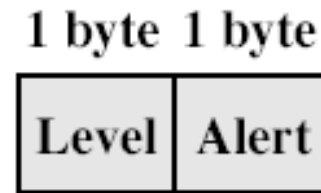

- Notify the receiving party that subsequent records will be protected under the just-negotiated cipherspec and keys.
- Consists of **a single message**, which consists of a single byte with the value 1.
- Causes pending state to become current - updating the cipher suite in use

1 byte

1

SSL/TLS Alert Protocol

- Conveys **SSL-related alerts** to peer entity
- Consists of two bytes – the first takes the value: warning (1) or fatal (2); the second contains a code that indicates the specific alert.

- ◆ **Fatal:** unexpected message, decompression failure, handshake failure, illegal parameter
 - SSL immediately terminates the connection
- ◆ **Warning:** close notify (**the sender will not send any more message of this connection**), bad certificate, unsupported certificate, certificate revoked, certificate expired, certificate unknown.

SSL/TLS Record Protocol Services

- Provides two services for SSL connections

- ◆ Confidentiality:

- encrypt SSL payloads

- ◆ Message integrity:

- use a shared secret key to form MAC.

SSL/TLS Record Protocol Operation

- **Fragmentation:** message is fragmented into blocks of 2^{14} bytes or less
- **Compression (optional):** lossless and may not increase the content length by more than 1024 byte (for very short block, it is possible that the output is longer)

SSL/TLS Record Protocol Operation

- **MAC:** Compute the message authentication code over the compressed data.
- **Encryption:** the compressed message plus the MAC are encrypted using symmetric encryption.

HeartBleed Vulnerability

- Introduced into OpenSSL code in 2011 by Robin Seggelmann (a Ph.D. student at the University of Duisburg-Essen).
 - ◆ Seggleman implemented a “heartbeat” function into OpenSSL which allows one side to check if the other side is still up and running.
- Stephen Henson, in charge of OpenSSL core development, did not spot Seggelmann’s bug.
 - ◆ Result: the vulnerable code was introduced into the production version...persisted till 2014.

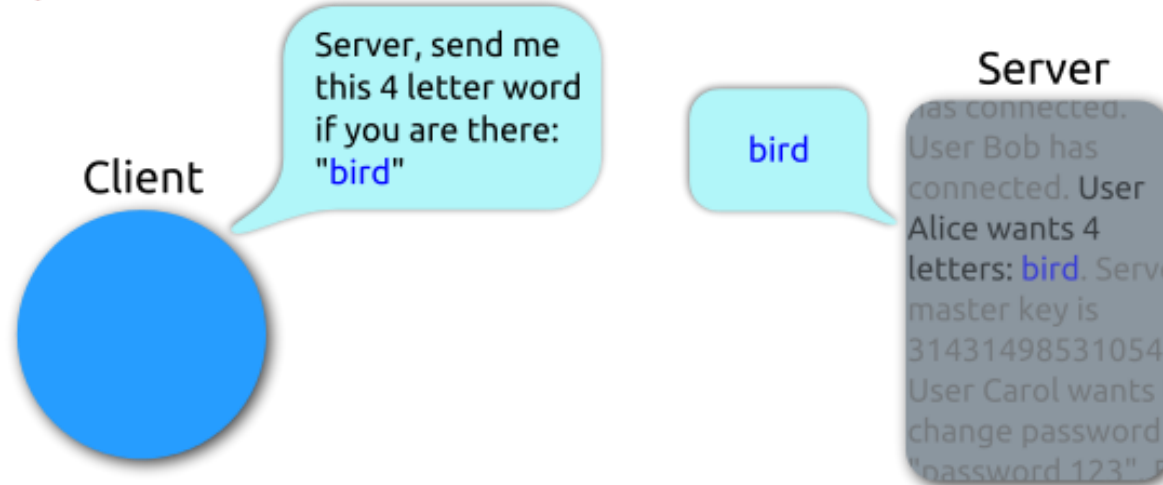

HeartBleed Vulnerability

- SSL heartbeats are used for one side (server or client) to check if the other side is alive and well.
 - ◆ Send an N byte message to the other side. The other side will echo the same N bytes back to the sender.
- The implementation bug:
 - ◆ The sender sends an $X < N$ byte message, but tells the receiver that the message is actually N bytes.
 - ◆ The other side will echo the X bytes and $N-X$ bytes in the memory adjacent to the first X bytes.
 - That memory can contain keys, certificates, passwords, and other information.
 - Can steal up to 64 KB of data per heartbeat message.

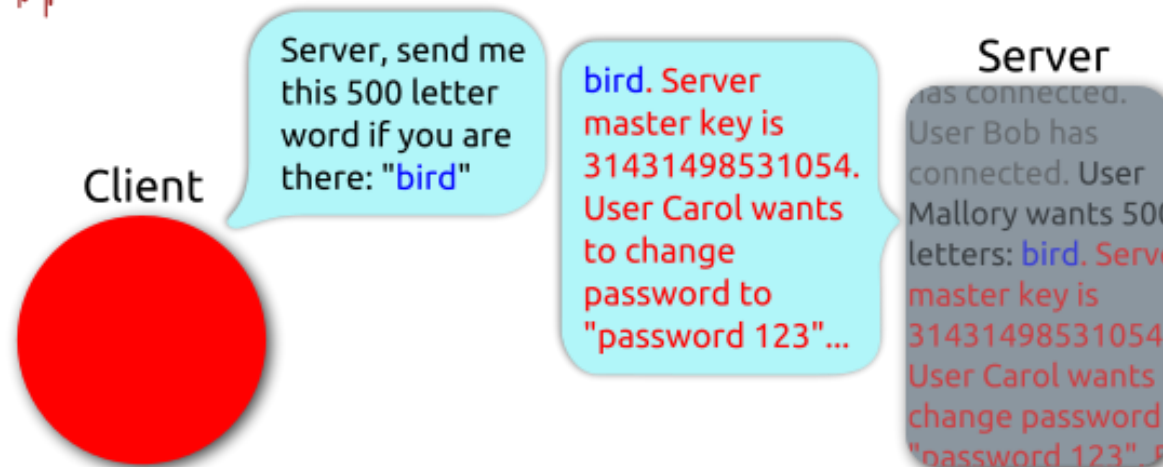

HeartBleed Vulnerability Example:

Heartbeat – Normal usage

Heartbeat – Malicious usage

Password Management

Password Management

- **Front-line defense** against intruders
- Users supply both:
 - ◆ **login** – determines whether the user is authorized to gain access to a system, and the privileges of that user.
 - ◆ **password** – to identify them
- Should protect password file on system
 - ◆ **One-way function**: the system stores only the value of a function based on the user's password.
 - ◆ **Access control**: access to the password file is limited to one or a very few accounts.

Unix Password Management

- The user selects a password.
- Multiple encryption/hashing schemes supported for storing the password
- Good explanation: http://en.wikipedia.org/wiki/Shadow_password

Linux Password and Verification: Basic Idea

- A system should *never* store passwords in plaintext
 - ◆ If access controls fail, the passwords are divulged
- **Better idea:** we could store passwords in an encrypted database
 - ◆ **Problem:** if the attacker compromises the key, they will be able to obtain all the passwords
- **Best idea:** store the hashes of passwords!
 - ◆ Hash functions are **one-way**, so even if the attacker compromises the password database, they will not be able to directly obtain the passwords

Linux Password and Verification: Basic Idea

● Hashed passwords: basic idea:

- ◆ When a user account is created, the users original password is hashed and stored in the password database that maps user IDs to password hashes

Linux Password and Verification: Basic Idea

- **Example:** user Bob **creates** a password:
 - ◆ Types password
 - ◆ The password is hashed and is stored in the database

Password Database

User ID	Password Hash
Bob	77d7f045034e630f2625a8f875abf801 679f78391bb58518a1eba3bbf9b92d72
Alice	...

SHA-256(m23dd_sz%45) m23dd_sz%45

Linux Password and Verification: Basic Idea

● **Example:** user Bob **tries to log in** a password:

- ◆ Types username/password
- ◆ The password is hashed
- ◆ The hash of the entered password is matched against Bob's hash in the database

Password Database

User ID	Password Hash
Bob	77d7f045034e630f2625a8f875abf801679f78391bb58518a1eba3bbf9b92d72
Alice	...

bf9b92d72

Username: Bob
Password: m23dd_sz%45

SHA-256(m23dd_sz%45)

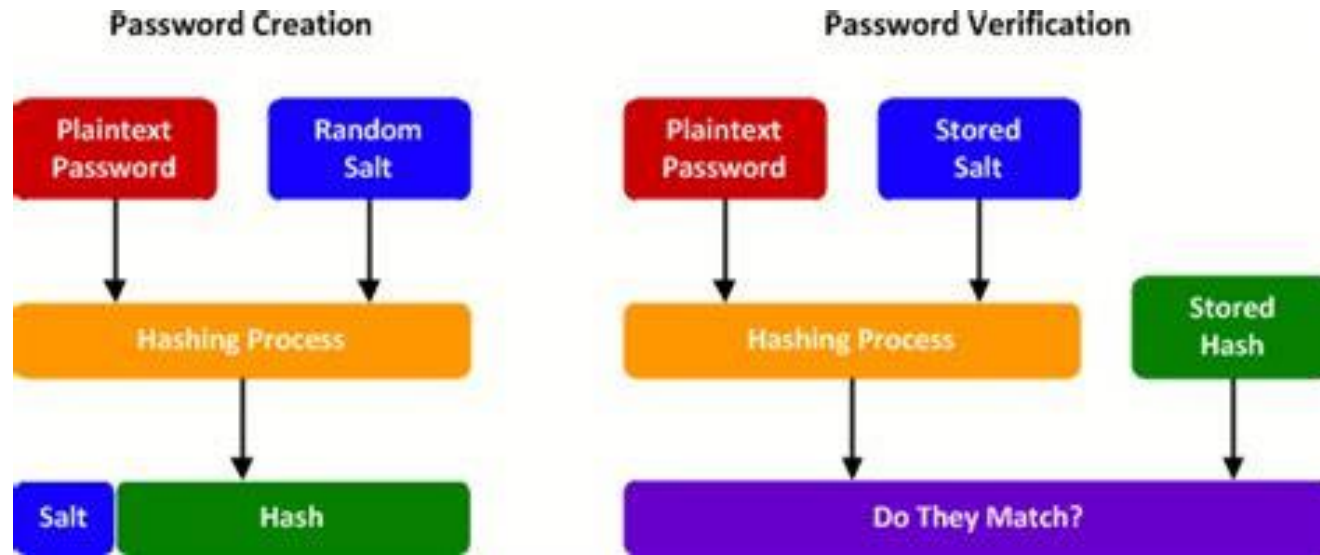

Linux Password and Verification: Basic Idea

- **Problem:** since users tend to choose weak, predictable passwords, the attacker:
 - ◆ 1. Can **create a dictionary** of hashes of common passwords (a.k.a rainbow table)
 - E.g., a two-column mapping a password to a hash
 - ◆ 2. **Steal the password database** and **match the hashes in the database against the hashes in the dictionary**
 - ◆ 3. If a match is found, the attacker now **knows the password**
 - NOTE: if two users have the same hash, the attacker knows they have the same password
- **Countermeasure?** Next slide...

Linux Password and Verification: Basic Idea

- **Solution: password salting**: is a standard technique used to improve security of hashed password storage
 - ◆ A **random value known as salt**, is added to the password prior to hashing it
 - ◆ A column is added to the password database that contains the salt

Linux Password and Verification: Basic Idea

● Salting: Basic idea:

◆ Storing the password: the user provides the password

- Before hashing the password, a Salt value (a random number) is added to the password to help frustrate rainbow table attacks.
- The password and salt are stored in the password database indexed by the user name

◆ Verification: the user enters user name and password. The entry for the user is looked up in the database. If the associated $\text{hash}(\text{entered password} \parallel \text{salt}) == \text{hash}$ in the database, the password is correct

Managing Passwords - Education

● Benefits of salting:

- ◆ If the attacker has only the salted hash:
 - 10 alphanumeric character password has 26^{10} possible hashes
 - 10 alphanumeric password + 12-bit salt has $26^{10} * 2^{12}$ possible hashes
- ◆ If the attacker has the salted hash and the salt, **two users with the same passwords will different hashes.**

Linux Password and Verification: Basic Idea

- **Real-world:** In Linux the passwords and salts are stored in the root-only accessible `/etc/shadow` file
- **Example:** each row represents an entry for a user:

Linux Password and Verification: Basic Idea

- Real-world: In Linux the passwords and salts are stored in the root-only accessible `/etc/shadow` file
- **Example:** Meaning of an entry (image source: <https://www.cyberciti.biz/faq/understanding-etcshadow-file/>):

vivek:\$1\$fnfffc\$pgteyHdicpGOffXX4ow#5:13064:0:99999:7:::

1 2 3 4 5 6

The diagram illustrates the fields of a Linux shadow file entry. The entry is 'vivek:\$1\$fnfffc\$pgteyHdicpGOffXX4ow#5:13064:0:99999:7:::'. Arrows point from the following fields to numbers 1 through 6: 1. 'vivek' (username), 2. '\$1\$fnfffc\$pgteyHdicpGOffXX4ow#5' (password and salt), 3. '13064' (last password change time), 4. '0' (minimum password age), 5. '99999' (maximum password age), and 6. '7' (warning time before password expiration).

- 1. **User name:** the user name to whom this password belongs

Linux Password and Verification: Basic Idea

- Real-world: In Linux the passwords and salts are stored in the root-only accessible `/etc/shadow` file
- Example:** Meaning of an entry:

vivek:\$1\$fnfffc\$pgteyHdicpGOfffXX4ow#5:13064:0:99999:7:::

1	2	3	4	5	6
---	---	---	---	---	---

- 2. **Hashed password.** The format of the password is `idsalt$hashed` where:
 - ◆ `ld` is the hashing algorithm
 - `1` is MD5 (the one used in the example)
 - `$2a$` is Blowfish
 - `$2y$` is Blowfish
 - `5` is SHA-512
 - `6` is SHA-512

Linux Password and Verification: Basic Idea

- Real-world: In Linux the passwords and salts are stored in the root-only accessible `/etc/shadow` file
- Example:** Meaning of an entry:

vivek:\$1\$fnfffc\$PgtEyHdicpGOfffXX4ow#5:13064:0:99999:7:::

1 2 3 4 5 6

- 2. **Hashed password.** The format of the password is `idsalt$hashed` where:
 - ◆ `$salt$` is the salt value (fnfffc in the example)

Linux Password and Verification: Basic Idea

- Real-world: In Linux the passwords and salts are stored in the root-only accessible `/etc/shadow` file
- Example:** Meaning of an entry:

vivek:\$1\$fnfffc\$pGteyHdicpGOfffXX4ow#5:13064:0:99999:7:::

1 2 3 4 5 6

- 2. **Hashed password.** The format of the password is `idsalt$hashed` where:
 - `$hashed$` is the hash value of the combined salt and hash (pGteyHdicpGOfffXX4ow#5 in the example)

Linux Password and Verification: Basic Idea

- Real-world: In Linux the passwords and salts are stored in the root-only accessible `/etc/shadow` file
- Example:** Meaning of an entry:

vivek:\$1\$fnfffc\$GteyHdicpGOfffXX4ow#5:13064:0:99999:7:::

1 2 3 4 5 6

The diagram illustrates the fields of a Linux shadow file entry. The entry is "vivek:\$1\$fnfffc\$GteyHdicpGOfffXX4ow#5:13064:0:99999:7:::". Arrows point from the following fields to numbers 1 through 6: 1. Username "vivek", 2. Password and salt "\$1\$fnfffc\$GteyHdicpGOfffXX4ow", 3. Days since last change "5", 4. Minimum days between changes "13064", 5. Maximum days between changes "0", 6. Inactivity period "99999". The last two fields "7:::" are not numbered.

- 3. **Last password change:** The date of the last password change as number of days elapsed since Jan 1, 1970 (Unix time). A value of 0 means the user must change the password at the next login.

Linux Password and Verification: Basic Idea

- Real-world: In Linux the passwords and salts are stored in the root-only accessible `/etc/shadow` file
- Example:** Meaning of an entry:

vivek:\$1\$fnfffc\$pgteyHdicpGOfffXX4ow#5:13064:0:99999:7:::

1 2 3 4 5 6

The diagram illustrates the fields of a Linux shadow file entry. The entry is: vivek:\$1\$fnfffc\$pgteyHdicpGOfffXX4ow#5:13064:0:99999:7:::. Arrows point from the following fields to numbers 1 through 6: 1. Username (vivek), 2. Password and salt (\$1\$fnfffc\$pgteyHdicpGOfffXX4ow#5), 3. Last password change time (13064), 4. Minimum number of days between changes (0), 5. Maximum number of days between changes (99999), and 6. Number of days left before change (7).

- 4. **Minimum:** The minimum number of days required between password changes (the number of days left before the user must change their password)

Linux Password and Verification: Basic Idea

- Real-world: In Linux the passwords and salts are stored in the root-only accessible `/etc/shadow` file
- **Example:** Meaning of an entry:

vivek:\$1\$fnfffc\$GteyHdicpGOfffXX4ow#5:13064:0:99999:7:::

The diagram illustrates the components of a Linux shadow file entry. The entry is: `vivek:1fnfffc$GteyHdicpGOfffXX4ow#5:13064:0:99999:7:::`. Arrows point from specific parts of the entry to numbered labels below:

- 1: Points to the username `vivek`.
- 2: Points to the salt and encrypted password `1fnfffc$GteyHdicpGOfffXX4ow#5`.
- 3: Points to the field `13064`.
- 4: Points to the field `0`.
- 5: Points to the field `99999`.
- 6: Points to the field `7`.

- 5. **Maximum:** The number of days the password is valid before the user must change it

Linux Password and Verification: Basic Idea

- Real-world: In Linux the passwords and salts are stored in the root-only accessible `/etc/shadow` file
- Example:** Meaning of an entry:

vivek:\$1\$fnfffc\$pgteyHdicpGOfffXX4ow#5:13064:0:99999:7:::

1 2 3 4 5 6

The diagram illustrates the fields of a Linux shadow file entry. The entry is: vivek:\$1\$fnfffc\$pgteyHdicpGOfffXX4ow#5:13064:0:99999:7:::. Arrows point from the following fields to numbers 1 through 6: 1. Username (vivek), 2. Password hash (\$1\$fnfffc\$pgteyHdicpGOfffXX4ow#5), 3. Last password change time (13064), 4. Minimum number of days between password changes (0), 5. Maximum number of days between password changes (99999), and 6. Number of days before password expires (7).

- 6. **Warn:** The number of days before the password is to expire that the user is warned about the need to change the password.

Linux Password and Verification: Basic Idea

- Real-world: In Linux the passwords and salts are stored in the root-only accessible `/etc/shadow` file
- Example:** Meaning of an entry:

vivek:\$1\$fnfffc\$GteyHdicpGOfffXX4ow#5:13064:0:99999:7:::

1 2 3 4 5 6

- 7. **Inactive:** The number of days after password expiration after which the account is disabled.

Linux Password and Verification: Basic Idea

- Real-world: In Linux the passwords and salts are stored in the root-only accessible `/etc/shadow` file
- **Example:** Meaning of an entry:

vivek:\$1\$fnfffc\$GteyHdicpGOfffXX4ow#5:13064:0:99999:7:::

1 2 3 4 5 6

The diagram illustrates the fields of a Linux shadow file entry. The entry is: vivek:\$1\$fnfffc\$GteyHdicpGOfffXX4ow#5:13064:0:99999:7:::. Arrows point from the following fields to numbers 1 through 6: 1. Username (vivek), 2. Password hash (\$1\$fnfffc\$GteyHdicpGOfffXX4ow#5), 3. Last password change time (13064), 4. Minimum number of days between password changes (0), 5. Maximum number of days between password changes (99999), and 6. Password inactivity time (7).

- 8. **Expire:** The date of the account expiration (as days since January 1, 1970)

Managing Passwords - Computer Generated

- Let computer create passwords

Managing Passwords - Computer Generated

- Let computer create passwords
 - ◆ If the passwords are quite **random** in nature, users will not be able to remember them.
 - ◆ Even if the password is **pronounceable**, the user may have difficulty remembering it.
 - ◆ Have history of poor user acceptance.

Managing Passwords - Reactive Checking

- Periodically run password guessing tools
- Cracked passwords are **disabled**
- But is resource intensive
- Bad passwords are vulnerable till found

Managing Passwords - Proactive Checking

- Most promising approach to improving password security
- Allow users to select own password
- But have system verify it is acceptable
 - ◆ Simple rule enforcement
 - ◆ Compare against **dictionary** of bad passwords
